

Installing Arduino IDE on a Linux Machine

Step 1: Download the installation script

Download the `install_arduino.sh` script to your Linux machine and save it in your **Downloads** folder.

Step 2: Open a Terminal

Open a terminal window.

Step 3: Navigate to the Downloads folder

```
cd ~/Downloads
```

If you saved the script in a different location, navigate to that folder instead.

Step 4: Run the installation script

Execute the script using Bash:

```
bash install_arduino.sh
```

The script will:

- Create an `Applications` folder in your home directory (if it does not already exist).
- Download the latest Arduino IDE AppImage from the official Arduino website.
- Save it as `~/Applications/ArduinoIDE.AppImage`.
- Make the AppImage executable.

Step 5: Launch Arduino IDE

After the installation finishes, start the Arduino IDE by running:

```
~/Applications/ArduinoIDE.AppImage
```

Alternatively, open your file manager, navigate to the `Applications` folder in your home directory, and double-click `ArduinoIDE.AppImage`.

Troubleshooting

"Permission denied"

If you receive a **Permission denied** error when launching the AppImage, run:

```
chmod +x ~/Applications/ArduinoIDE.AppImage
```

Then try launching it again:

```
~/Applications/ArduinoIDE.AppImage
```

"wget: command not found"

Install `wget` using your package manager.

For Ubuntu or Debian:

```
sudo apt update  
sudo apt install wget
```

Then rerun the installation script.

Verify the installation

If the Arduino IDE opens successfully, the installation is complete. You can connect your Arduino board and begin creating or uploading sketches.
